# Basic Aspects of MC Applications

- Stochastic – i.e., some element of randomness.
- Contrast with standard integration algorithms.
- When is MC useful?

# Problem from Friday Class

- Compute an integral of  $p(q)f(q)dq$  where  $p(q)$  is a probability distribution.
- You could do it by sampling  $\{q_1, q_2, q_3, \dots\}$  from the distribution  $p(q)$ , and then just averaging

$$\langle f \rangle \sim \{f(q_1) + f(q_2) + \dots + f(q_N)\} / N$$

and that as  $N$  gets large this average will approach the value of the desired integral.

# Basic MC Application – 2d integration

- Calculate value of Pi
- <http://www.eveandersson.com/pi/monte-carlo-demo.tcl>

# Comparisons of accuracy

- MC – accuracy  $\sim N^{-0.5}$
- Other methods – accuracy  $\sim N^{-1/d}$

# Problem with Random States

- Ex: calculation for area of hyper-sphere for calculation of Pi. Chance of 'hit'  $\rightarrow 0$ .
- Importance Sampling – concentrates sampling in regions of higher probability

# Idea of Phase Space

- Represents the entire set of states that can be occupied by the 'system'.
- Ex: all values for which  $p(x)$  is not 0.
- What if phase space represents a very small portion of the randomly generated possibilities?: ex. Bonded molecule.

# Ergodicity

- MC often used to simulate time-dependent processes, although there is no 'time' in MC simulations.
- Ergodic Theorem: Phase space average is identical to the time average.

# Metropolis Method

- If the attempted move lowers the energy, it is automatically accepted.
- If the attempted move increases the energy, it is accepted with probability  $p(x) = \exp(\Delta E/kT)$
- Only need RELATIVE probabilities

# Metropolis Method (cont.)

- The attempted configuration represents a deviation from a previous configuration.
- Important: If a move is rejected the 'old' state is counted again.
- Does this make sense?

# MC vs. MD

- Equilibrium vs. Dynamics

# Orientation of Polymers using MC

- MD cannot typically probe large (ms) time scales
- MC can find equilibrium sets of configurations – typically shorter correlations because of the possibility of unphysical moves.

# Example – evolution of torsions using MC

- Statistical sampling of the phase space
