

14.581 International Trade
— Lecture 16: Gravity Models (Theory) —

Today's Plan

- 1 The Simplest Gravity Model: Armington
- Gravity Models and the Gains from Trade: ACR (2012)
- Beyond ACR's (2012) Equivalence Result: CR (2013)

1. The Simplest Gravity Model: Armington

The Armington Model

Image courtesy of rdpeyton on flickr. CC NC-BY-SA

The Armington Model: Equilibrium

- Labor endowments

$$L_i \text{ for } i = 1, \dots, n$$

- CES utility \Rightarrow CES price index

$$P_j^{1-\sigma} = \sum_{i=1}^n (w_i \tau_{ij})^{1-\sigma}$$

- Bilateral trade flows follow **gravity equation**:

$$X_{ij} = \frac{(w_i \tau_{ij})^{1-\sigma}}{\sum_{l=1}^n (w_l \tau_{lj})^{1-\sigma}} w_j L_j$$

- In what follows $\varepsilon \equiv -\frac{d \ln X_{ij}/X_{ij}}{d \ln \tau_{ij}} = \sigma - 1$ denotes the **trade elasticity**
- Trade balance

$$\sum_i X_{ji} = w_j L_j$$

The Armington Model: Welfare Analysis

- **Question:**

Consider a foreign shock: $L_i \rightarrow L'_i$ for $i \neq j$ and $\tau_{ij} \rightarrow \tau'_{ij}$ for $i \neq j$. How do foreign shocks affect real consumption, $C_j \equiv w_j / P_j$?

- Shephard's Lemma implies

$$d \ln C_j = d \ln w_j - d \ln P_j = - \sum_{i=1}^n \lambda_{ij} (d \ln c_{ij} - d \ln c_{jj})$$

with $c_{ij} \equiv w_i \tau_{ij}$ and $\lambda_{ij} \equiv X_{ij} / w_j L_j$.

- Gravity implies

$$d \ln \lambda_{ij} - d \ln \lambda_{jj} = -\varepsilon (d \ln c_{ij} - d \ln c_{jj}).$$

The Armington Model: Welfare Analysis

- Combining these two equations yields

$$d \ln C_j = \frac{\sum_{i=1}^n \lambda_{ij} (d \ln \lambda_{ij} - d \ln \lambda_{jj})}{\varepsilon}.$$

- Noting that $\sum_i \lambda_{ij} = 1 \implies \sum_i \lambda_{ij} d \ln \lambda_{ij} = 0$ then

$$d \ln C_j = -\frac{d \ln \lambda_{jj}}{\varepsilon}.$$

- Integrating the previous expression yields ($\hat{x} = x'/x$)

$$\hat{C}_j = \hat{\lambda}_{jj}^{-1/\varepsilon}.$$

The Armington Model: Welfare Analysis

- In general, predicting $\hat{\lambda}_{jj}$ requires (computer) work
 - We can use exact hat algebra as in DEK (Lecture #3)
 - Gravity equation + data $\{\lambda_{ij}, Y_j\}$, and ε
- But predicting how bad would it be to shut down trade is easy...
 - In autarky, $\lambda_{jj} = 1$. So

$$C_j^A / C_j = \lambda_{jj}^{1/(\sigma-1)}$$

- Thus **gains from trade** can be computed as

$$GT_j \equiv 1 - C_j^A / C_j = 1 - \lambda_{jj}^{1/\varepsilon}$$

The Armington Model: Gains from Trade

- Suppose that we have estimated trade elasticity using gravity equation
 - Central estimate in the literature is $\varepsilon = 5$
- We can then estimate gains from trade:

	λ_{jj}	% GT_j
Canada	0.82	3.8
Denmark	0.74	5.8
France	0.86	3.0
Portugal	0.80	4.4
Slovakia	0.66	7.6
U.S.	0.91	1.8

2. Gravity Models and the Gains from Trade: ACR (2012)

- **New Trade Models**

- Micro-level data have lead to **new questions** in international trade:
 - How many firms export?
 - How large are exporters?
 - How many products do they export?
- New models highlight **new margins** of adjustment:
 - From inter-industry to intra-industry to intra-firm reallocations

- **Old question:**

- How large are the gains from trade (GT)?

- **ACR's question:**

- How do new trade models affect the magnitude of GT?

ACR's Main Equivalence Result

- ACR focus on gravity models
 - PC: Armington and Eaton & Kortum '02
 - MC: Krugman '80 and many variations of Melitz '03
- Within that class, welfare changes are ($\hat{x} = x'/x$)

$$\hat{C} = \hat{\lambda}^{1/\varepsilon}$$

- **Two sufficient statistics** for welfare analysis are:
 - Share of domestic expenditure, λ ;
 - Trade elasticity, ε
- **Two views** on ACR's result:
 - Optimistic: welfare predictions of Armington model are more robust than you thought
 - Pessimistic: within that class of models, micro-level data do not matter

Primitive Assumptions

Preferences and Endowments

- **CES utility**

- Consumer price index,

$$P_i^{1-\sigma} = \int_{\omega \in \Omega} p_i(\omega)^{1-\sigma} d\omega,$$

- **One factor of production:** labor

- $L_i \equiv$ labor endowment in country i
- $w_i \equiv$ wage in country i

- **Linear cost function:**

$$C_{ij}(\omega, t, q) = \underbrace{qw_i \tau_{ij} \alpha_{ij}(\omega) t^{\frac{1}{1-\sigma}}}_{\text{variable cost}} + \underbrace{w_i^{1-\beta} w_j^\beta \zeta_{ij} \phi_{ij}(\omega) m_{ij}(t)}_{\text{fixed cost}},$$

q : quantity,

τ_{ij} : iceberg transportation cost,

$\alpha_{ij}(\omega)$: good-specific heterogeneity in variable costs,

ζ_{ij} : fixed cost parameter,

$\phi_{ij}(\omega)$: good-specific heterogeneity in fixed costs.

- **Linear cost function:**

$$C_{ij}(\omega, t, q) = qw_i \tau_{ij} \alpha_{ij}(\omega) t^{\frac{1}{1-\sigma}} + w_i^{1-\beta} w_j^\beta \zeta_{ij} \phi_{ij}(\omega) m_{ij}(t)$$

$m_{ij}(t)$: cost for endogenous destination specific technology choice, t ,

$$t \in [\underline{t}, \bar{t}] , m'_{ij} > 0, m''_{ij} \geq 0$$

- **Linear cost function:**

$$C_{ij}(\omega, t, q) = qw_i \tau_{ij} \alpha_{ij}(\omega) t^{\frac{1}{1-\sigma}} + w_i^{1-\beta} w_j^\beta \zeta_{ij} \phi_{ij}(\omega) m_{ij}(t)$$

- Heterogeneity across goods

$$G_j(\alpha_1, \dots, \alpha_n, \phi_1, \dots, \phi_n) \equiv \left\{ \omega \in \Omega \mid \alpha_{ij}(\omega) \leq \alpha_i, \phi_{ij}(\omega) \leq \phi_i, \forall i \right\}$$

Primitive Assumptions

Market Structure

- **Perfect competition**

- Firms can produce any good.
- No fixed exporting costs.

- **Monopolistic competition**

- Either firms in i can pay $w_i F_i$ for monopoly power over a random good.
- Or exogenous measure of firms, $\bar{N}_i < \bar{N}$, receive monopoly power.

- Let N_i be the measure of goods that can be produced in i

- Perfect competition: $N_i = \bar{N}$
- Monopolistic competition: $N_i < \bar{N}$

Macro-Level Restrictions

Trade is Balanced

- Bilateral trade flows are

$$X_{ij} = \int_{\omega \in \Omega_{ij} \subset \Omega} x_{ij}(\omega) d\omega$$

- **R1** For any country j ,

$$\sum_{i \neq j} X_{ij} = \sum_{i \neq j} X_{ji}$$

- Trivial if perfect competition or $\beta = 0$.
- Non trivial if $\beta > 0$.

Macro-Level Restrictions

Profit Share is Constant

- **R2** For any country j ,

$$\Pi_j / (\sum_{i=1}^n X_{ji}) \text{ is constant}$$

where Π_j : aggregate profits gross of entry costs, $w_j F_j$, (if any)

- Trivial under perfect competition.
- Direct from Dixit-Stiglitz preferences in Krugman (1980).
- Non-trivial in more general environments.

Macro-Level Restriction

CES Import Demand System

- *Import demand system*

$$(\mathbf{w}, \mathbf{N}, \boldsymbol{\tau}) \rightarrow \mathbf{X}$$

- **R3**

$$\varepsilon_j^{i'} \equiv \partial \ln (X_{ij} / X_{jj}) / \partial \ln \tau_{i'j} = \begin{cases} \varepsilon < 0 & i = i' \neq j \\ 0 & \text{otherwise} \end{cases}$$

- Note: symmetry and separability.

Macro-Level Restriction

CES Import Demand System

- The *trade elasticity* ε is an *upper-level* elasticity: it combines
 - $x_{ij}(\omega)$ (*intensive margin*)
 - Ω_{ij} (*extensive margin*).
- R3 \implies complete specialization.
- R1-R3 are not necessarily independent
 - If $\beta = 0$ then R3 \implies R2.

Macro-Level Restriction

Strong CES Import Demand System (AKA Gravity)

- **R3'** The IDS satisfies

$$X_{ij} = \frac{\chi_{ij} \cdot M_i \cdot (w_i \tau_{ij})^\varepsilon \cdot Y_j}{\sum_{i'=1}^n \chi_{i'j} \cdot M_{i'} \cdot (w_{i'} \tau_{i'j})^\varepsilon}$$

where χ_{ij} is independent of $(\mathbf{w}, \mathbf{M}, \boldsymbol{\tau})$.

- Same restriction on $\varepsilon_j^{i'}$ as R3 but, but additional structural relationships

- State of the world economy:

$$\mathbf{Z} \equiv (\mathbf{L}, \tau, \xi)$$

- *Foreign shocks*: a change from \mathbf{Z} to \mathbf{Z}' with no domestic change.

- **Proposition 1:** *Suppose that R1-R3 hold. Then*

$$\widehat{W}_j = \widehat{\lambda}_{jj}^{1/\varepsilon}.$$

- Implication: 2 sufficient statistics for welfare analysis $\widehat{\lambda}_{jj}$ and ε
- New margins affect structural interpretation of ε
 - ...and composition of gains from trade (GT)...
 - ... but size of GT is the same.

Gains from Trade Revisited

- Proposition 1 is an *ex-post* result... a simple *ex-ante* result:
- **Corollary 1:** *Suppose that R1-R3 hold. Then*

$$\widehat{W}_j^A = \lambda_{jj}^{-1/\varepsilon}.$$

Equivalence (II)

- A stronger ex-ante result for **variable trade costs** under R1-R3':
- **Proposition 2:** *Suppose that R1-R3' hold. Then*

$$\widehat{W}_j = \widehat{\lambda}_{jj}^{1/\varepsilon}$$

where

$$\widehat{\lambda}_{jj} = \left[\sum_{i=1}^n \lambda_{ij} (\widehat{w}_i \widehat{\tau}_{ij})^\varepsilon \right]^{-1},$$

and

$$\widehat{w}_i = \sum_{j=1}^n \lambda_{ij} \widehat{w}_j Y_j (\widehat{w}_i \widehat{\tau}_{ij})^\varepsilon$$

- ε and $\{\lambda_{ij}\}$ are sufficient to predict W_j (ex-ante) from $\widehat{\tau}_{ij}$, $i = j$.

- ACR consider models featuring:
 - (i) Dixit-Stiglitz preferences;
 - (ii) one factor of production;
 - (iii) linear cost functions; and
 - (iv) perfect or monopolistic competition;

with three macro-level restrictions:

- (i) trade is balanced;
 - (ii) aggregate profits are a constant share of aggregate revenues; and
 - (iii) a CES import demand system.
- Equivalence for ex-post welfare changes and GT
 - under R3' equivalence carries to ex-ante welfare changes

3. Beyond ACR's (2012) Equivalence Result: CR (2013)

- **Other Gravity Models:**

- Multiple Sectors
- Tradable Intermediate Goods
- Multiple Factors
- Variable Markups

- **Beyond Gravity:**

- PF's sufficient statistic approach
- Revealed preference argument (Bernhofen and Brown 2005)
- More data (Costinot and Donaldson 2011)

Back to Armington

- 1 Add multiple sectors
- 2 Add traded intermediates

- Nested CES: Upper level EoS ρ and lower level EoS ε_s
- Recall gains for Canada of 3.8%. Now gains can be much higher:
 $\rho = 1$ implies $GT = 17.4\%$

Tradable intermediates, GT

- Set $\rho = 1$, add tradable intermediates with Input-Output structure
- Labor shares are $1 - \alpha_{j,s}$ and input shares are $\alpha_{j,ks}$ ($\sum_k \alpha_{j,ks} = \alpha_{j,s}$)

Tradable intermediates, GT

	$\% GT_j$	$\% GT_j^{MS}$	$\% GT_j^{IO}$
Canada	3.8	17.4	30.2
Denmark	5.8	30.2	41.4
France	3.0	9.4	17.2
Portugal	4.4	23.8	35.9
U.S.	1.8	4.4	8.3

Combination of micro and macro features

- In Krugman, free entry \Rightarrow scale effects associated with total sales
- In Melitz, additional scale effects associated with market size
- In both models, trade may affect entry and fixed costs
- All these effects do not play a role in the one sector model
- With multiple sectors and traded intermediates, these effects come back

From GT to trade policy evaluation

- Back to $\{\lambda_{ij}, Y_j\}$, ε and $\{\hat{\tau}_{ij}\}$ to get implied $\hat{\lambda}_{ij}$
- This is what CGE exercises do
- Contribution of recent quantitative work:
 - Link to theory—“mid-sized models”
 - Model consistent estimation
 - Quantify mechanisms

- **Mechanisms that matter for GT:**

- Multiple sectors, tradable intermediates
- Market structure matters, but in a more subtle way

- **Trade policy in gravity models:**

- Good approximation to optimal tariff is $1/\varepsilon \approx 20\%$ (related to Gros 87)
- Large range for which countries gain from tariffs
- Small effects of tariffs on other countries

For Future Research

- Treatment of capital goods
- Modeling of trade imbalances
- Fit of model
- Relation with micro studies
- Relation with other non-gravity approaches
