8.21 Lecture 3

Mechanical Energy

September 14, 2009

Mechanical Energy

Transport:

~ 28% of U.S. energy use

~ 30 EJ/year

~ 1/3 of U.S. CO₂ output

Elementary mechanics is relevant for understanding transport:

• Kinetic Energy

• Potential Energy

• Friction + air resistance

1. Kinetic Energy

Kinetic Energy of a mass m moving at speed v : $E_{\text{kin}} = \frac{1}{2}mv^2$

baseball @
100 mph

$$E_{\text{kin}} = \frac{1}{2} (5 \text{ oz}) (100 \text{ mph})^2 \cong \frac{1}{2} (150 \text{ g}) (160 \text{ km}/3600 \text{ s})^2$$
$$\cong \frac{1}{2} (0.15 \text{ kg}) (44 \text{ m/s})^2 \cong 150 \text{ J}$$

100 pitches $\cong 15 \text{ kJ} \ll 10 \text{ MJ}$ daily human food energy

Camry w/4
passengers

$$E_{\text{kin}} = \frac{1}{2} (4000 \text{ lb}) (60 \text{ mph})^2$$
$$\cong \frac{1}{2} (1800 \text{ kg}) (27 \text{ m/s})^2 \cong 700 \text{ kJ}$$

Transport Energy Example: ROAD TRIP!

Take Camry + 4 passengers, Boston New York

Compute energy used: Distance = 210 miles

30 miles/gallon \Rightarrow 7 gallons \times 120 MJ/gallon \cong 840 MJ
Camry w/4
passengers

Where does the energy go?

 $\Rightarrow E_{\text{kin}} = \frac{1}{2}mv^2 \cong 0.7 \text{ MJ}$

Engine efficiency? (25%: 840 \rightarrow 210 MJ)

Friction + air resistance?

Hills?

Question: how much energy expenditure is really necessary?

2. Potential Energy

Fundamental Principle: Energy is CONSERVED

Potential Energy: energy stored in a configuration of objects interacting through forces

Motion against a force (*e.g.* roll ball uphill)

kinetic energy \rightarrow potential energy

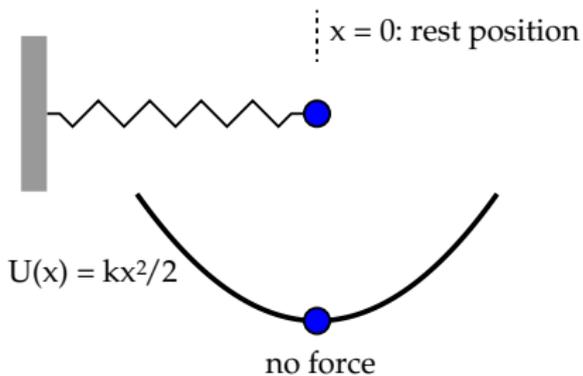

- Force points in direction of decreasing potential energy
- Motion in direction of force: potential E \rightarrow kinetic E

Example: spring  $U = \frac{1}{2}kx^2$

Potential Energy, Forces, and Work

Consider mass m subject to force $F = -kx$ from potential $U(x)$

Newton: $F = ma = m\ddot{x}$ (Transfers KE \leftrightarrow PE)

Force over distance **does work**

$$W = F \times d \Rightarrow W = \int F(x) dx$$

$$\text{Unpack: } \frac{dE_k}{dt} = m\dot{x}\ddot{x} = F \frac{dx}{dt}$$

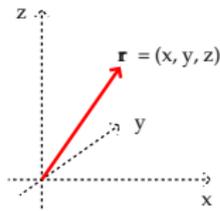

$$E_k + U = \text{const.} \Rightarrow \frac{dU}{dt} = -F \frac{dx}{dt}$$

So conservation of $E \Rightarrow U = -\int F dx$, or $F = -dU/dx$

Potential Energy and Vectors

For motion in a line, $F = m\ddot{x}$, potential $U \Rightarrow F = -dU(x)/dx$.

In 2D/3D, use vectors

Vector force: $\mathbf{F} = m\mathbf{a} = m \frac{d^2\mathbf{x}}{dt} = (m\ddot{x}, m\ddot{y}, m\ddot{z})$

Potential $U(x, y, z) \Rightarrow$

$$\mathbf{F} = -\nabla U = \left(-\frac{\partial U}{\partial x}, -\frac{\partial U}{\partial y}, -\frac{\partial U}{\partial z}\right)$$

Example: gravity

$$U = -\frac{GMm}{r}$$

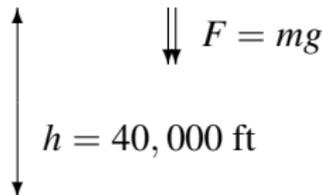

$$\mathbf{F} = -\nabla U = -\frac{GMm}{r^2} \hat{\mathbf{r}}$$

Potential Energy: Applications

- Airplane at altitude

747 at 900 km/h has $E_{\text{kin}} \cong \frac{1}{2}(350,000 \text{ kg})(250 \text{ m/s})^2 \cong 11 \text{ GJ}$

How about **potential energy**?

$$U = mgh \cong (350,000 \text{ kg})(9.8 \text{ m/s}^2)(12,000 \text{ m}) \cong 41 \text{ GJ}$$

Other examples of potential energy applications:

- Pump water uphill for storage
- Elevators, cranes, etc.

Back to the road trip!

- 4000 lb car at 60 mph \rightarrow 0.7 MJ
- Using 840 MJ of gasoline energy

Boston and New York are both basically at sea level

Is potential energy relevant? Yes!

<http://www.usatf.org/routes/mapi>

Recapture some lost energy on downhill—but not all!

Estimate effects of hills

- Assume:
- Constant speed $v = 60 \text{ mph} \cong 100 \text{ km/h}$
 - **50 ft** of elevation gain per mile
 - Lose 1/2 of energy used going up on downhill braking

$$\text{Energy needed/hill} = mgh = (1800 \text{ kg}) (9.8 \text{ m/s}^2) (15 \text{ m}) \cong \mathbf{260 \text{ kJ}}$$

$$\frac{1}{2} \times 260 \text{ kJ/mile} \times 210 \text{ miles} \cong \mathbf{27 \text{ MJ}}$$

So:

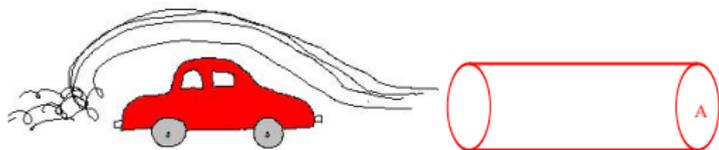

0.7	MJ to get started	}
27	MJ for hills	

Still \ll 210 MJ engine output
(assuming 25% efficiency)

What's left?

3. Air Resistance and Friction

How much energy is lost to air resistance?

Car collides with air molecules, sweeps into wake

Details complicated—**But basic idea is simple:**

Car sweeps out tube of area A , accelerates air to $\sim v$

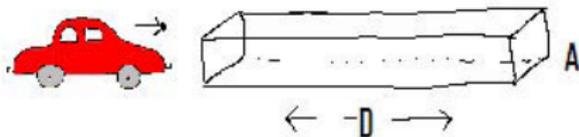

$$\Delta E_{\text{air}} \cong \frac{1}{2} c_d (\Delta m_{\text{air}}) v^2$$

c_d = drag coefficient

(typical car: $c_d \sim 1/3$)

$$\begin{aligned} \frac{dE_{\text{air}}}{dt} &\cong \frac{1}{2} c_d [(d(\text{vol})/dt) \times (\text{mass density } \rho)] v^2 \\ &\cong \frac{1}{2} c_d (Av) \rho v^2 \cong \frac{1}{2} c_d A \rho v^3 \end{aligned}$$

So total energy lost to air resistance in distance D is

$$W_{\text{air}} = \frac{1}{2}c_d(AD)\rho v^2$$

For the Toyota Camry going Boston \rightarrow New York

$$\frac{1}{2}(0.33)(2.66 \text{ m}^2 \times 330 \text{ km})(1.2 \text{ kg/m}^3)(27.7 \text{ m/s})^2 \cong 133 \text{ MJ!}$$

- Note: traveling at 80 mph $\Rightarrow (\times(4/3)^2) \Rightarrow 236 \text{ MJ}$
- Rolling resistance $\sim 1\%$ grade $\Rightarrow 54 \text{ MJ}$

Final energy accounting: Road trip to New York

2 MJ	kinetic energy (including 12 stoplights)
+27 MJ	potential energy of hills
+54 MJ	rolling resistance
+133 MJ	air resistance
<hr/>	
216 MJ	total

Energy in gasoline: **840 MJ**, energy efficiency $\sim 25\%$

Discuss internal combustion engine efficiency in [Lecture 10](#)

Note: City driving very different, dominated by acceleration/rolling resistance (& hills in SF)

U.S. uses 30 EJ/year for transport. **How to reduce?**

Simple physics → ideas for reducing transport energy cost

- $W_{\text{air}} \sim v^2$: Drive 60 not 80!
- $W_{\text{air}} \sim c_d A$: Streamline! Mass transit!
- Inflate your tires. (Decreases rolling resistance)
- More efficient engines (e.g. Toyota hybrid: Atkinson [L10])
- Regenerative brakes (capture hill, stoplight energy)
- $W_{\text{air}} \sim \rho$: vacuum tunnels? space?

In principle, with regenerative braking, and $\rho \rightarrow 0$,

$$E_{\text{transport}} \rightarrow 0!$$

SUMMARY

- Kinetic Energy = $\frac{1}{2}mv^2$
- Potential Energy: $U = mgh$, $\mathbf{F} = -\nabla U$
- Air Resistance $\frac{dW_{\text{air}}}{dt} = \frac{1}{2}c_d A \rho v^3$

	–car engines $\sim 25\%$ efficient	$840/4 = \underline{210 \text{ MJ}}$
• Auto	–air resistance	$\sim 135 \text{ MJ}$
transport:	–rolling resistance	$\sim 50 \text{ MJ}$
	–hills	$\sim 25 \text{ MJ}$
